

Project Nexus Overview

Welcome to the official documentation for Project Nexus. Project Nexus is a next-generation distributed caching engine designed to optimize cloud infrastructure. Our internal benchmarks show that implementing Nexus reduces database load by 40% across high-traffic microservices.

Terminology and Definitions

To understand the architecture, we must define the core components. A Cache Node is defined as a localized memory instance that holds frequently accessed queries. Cache Nodes synchronize using a gossip protocol to ensure eventually consistent data across the cluster without centralized coordination.

Methodology and Deployment

The methodology for rolling out Project Nexus involves a phased approach. The primary topics covered in our deployment strategy include node clustering, distributed load balancing, and zero-downtime migrations. We strongly recommend using a blue-green deployment strategy and monitoring the cluster health via the Nexus Dashboard.
